A) Materials and Methods

A purpose-built database containing all publicly available (GenBank Dec. 2006) coleopteran nucleotide sequences and a custom-designed bioinformatics pipeline enabled the automatic searching, filtration, alignment and combination of user specified genes to produce a taxonomically non-redundant, length restricted data set. Sequences (Table S1) were obtained with standard DNA sequencing protocols (S1). PCR amplification of SSU was performed in four overlapping fragments with primers described by Shull et al. (S2) (primer pairs: 18S5'-18Sb5.0, 18Sai-18Sb0.5, 18Sa1.0-18Sbi and 18Sa2.0-18S3'I). Amplification of partial mitochondrial *cox1* and *rrnL* genes was performed, respectively, with primer pairs C1-J-2183 (Jerry) and TL2-N-3014 (Pat) (S3), and LR-N-13398 and LR-J-12887 (S3) or LR-J-12961 (S4). The final data compilation included full-length SSU sequences for 1880 species (no missing taxa), corresponding to position 32 to 1959 in the *Drosophila melanogaster* sequence (S5), plus partial *rrnL* for 697 species and *cox1* for 726 species. The sequenced regions correspond to position 12884 to 13385 for *rrnL* and 2233 to 2957 for *cox1* on the *D. yakuba* map (S6). The proportion of missing single-nucleotide entries in the 1880-taxon data set was 22.3% (3606 positions in the aligned matrix of which 2039 parsimony informative) and 13.7% (2999 positions) in the 340-taxon data set. For the 1880-taxon data set the incongruence length difference index is 2.5% (the ‘extra homoplasy’ from combining the genes).

Length variable rRNA genes were aligned with BlastAlign (S7) with the blastn program under default settings (word size = 11; gap opening penalty = -5; gap extension penalty= -2) to produce a query-anchored multiple alignment where the maximum proportion of gaps allowed in a single sequence was set to 0.95 ($m = 0.95$). The SSU blast-based alignment was used in the final matrix whilst the *rrnL* alignment underwent an additional alignment step which utilized a parsimony tree from the blast-based alignment as a guide tree for a subsequent global alignment created with ClustalX (S8) under the default parameters without any manual modifications. The *cox1* sequences were also aligned by a single default run of ClustalX. Parsimony trees were obtained from the subsequent aligned matrix with an aggressive search protocol in TNT (S9) (Fig. S4). These searches utilized a combination of the parsimony ratchet, tree drifting, tree fusion and sectorial searches ($xmult = 100$) on a desktop PC (2.6 MHz Pentium processor, 768 Mb RAM) for 72 hours. The Rec-I-DCM3 disk covering method (S10) found no shorter trees when ‘divide and conquer’ techniques were applied. For the 340-taxon set SSU and *rrnL* were aligned with the aid of secondary structure predictions and unalignable sites were excluded. A total of 21 taxa were merged into chimeric terminals composed of congeneric species with complementary sequence information for the three genes, to reduce the amount of missing data. In all cases taxa

used to build chimaerae were confirmed to be monophyletic in the 1880-taxon analysis. Bayesian analyses were conducted with the parallel version of MrBayes vers. 3.1.2 (*S11*) on a 408 processor Opteron (1.8GHz, 2Gb memory) Beowulf cluster. A partition-specific GTR+I+ Γ model (selected by Modeltest; *S12*) was used for SSU, *rrnL*, and each codon position of *cox1* with random or user-defined starting tree, on the basis of traditional classification, for the Markov Chain. Eight runs over 10 million generations were evaluated on the basis of the harmonic mean estimator of the marginal likelihood and the PSRF convergence diagnostics in MrBayes (Fig. S5). Node ages were obtained for an all-compatible consensus tree with branch lengths averaged over the stationary phase of the bayesian run, with penalized likelihood in r8s (*S13*). The optimal smoothing parameter value was determined from a fossil-based model cross validation procedure (*S14*) with fossils implemented as minimum ages for seven clades (employing a range of dates for the earliest origin of geological strata to which these fossils were assigned; Table S6) and a fixed age for the ingroup (285 Mya). We used both multiple fossil calibration points (Table S6) and smoothing without fossil constraints followed by fixing the age of the ingroup to 285 Mya. Tentative 95% confidence intervals were obtained for a number of focal nodes applying the same procedure and optimal smoothing parameter value to 450 trees drawn at regular intervals from the stationary phase of the Markov chain (Fig. S5). Analyses were also repeated with a range of smoothing parameters to check robustness of inferences.

Species numbers and predominant feeding strategies of the main feeding stage (normally larvae) for each taxon were compiled from world catalogs, revisions and by consulting group experts and colleagues (Table S8). Parsimony reconstruction was used to identify independent origins of plant-feeding (Fig. S3). Polymorphic taxa that include plant-feeders, but are not predominantly herbivorous, (e.g. some subfamilies of Elateridae) were excluded from contrasts of species richness. Shifts in diversification rate were reconstructed as described (*S15*). This method calculates the probabilities of observing greater or equal imbalance in species numbers at each node under an equal rates null model (*S16*), defined as

$$2 \times (\text{number of species in smaller clade}) / (\text{sum of number of species in both clades} - 1).$$

The method was modified as in *S15* to correct for the trickle-down effect of recent radiations with outgroup comparisons. In brief, this method proceeds from the tips to the root of the tree and for any node displaying a significant probability of departure from the null model, it compares both sister clades in turn to the number of species in the outgroup clade to determine which clade represents the significant shift in diversification rate. The chosen clade has its species richness reset to the value of its sister clade, thus removing its influence on calculations at higher nodes. Full details are provided in the supplementary information online from *S15*. Average

diversification rates across terminal taxa were calculated as $\log(N)/\text{stem age}$ for each (sub)family from the calibrated trees. Stem age was calculated over smoothing parameters 1, 10, 100 and 1000 for both methods of calibrating dates.

B) Supporting Figures and Legends

Figure S1. Majority-rule consensus tree from Bayesian analysis. Tree created on the basis of 22,500 topologies sampled from the last 7.5 million generations (of 10 million in total) of the three best MCMC chains according to the likelihood harmonic mean (see Fig. S5). Numbers on branches represent the posterior probability of clades.

Figure S2. Terrestrial-to-aquatic transitions in the evolution of Coleoptera. Parsimony optimizations on the tree in Fig. 2 demonstrate 10 independent transitions to the aquatic medium in Coleoptera. Taxa were scored as aquatic if they contained species with aquatic habits in at least one life stage. Three transitions in Cucujiformia refer to lineages adapted to submerged plants rather than free-living in the aquatic medium.

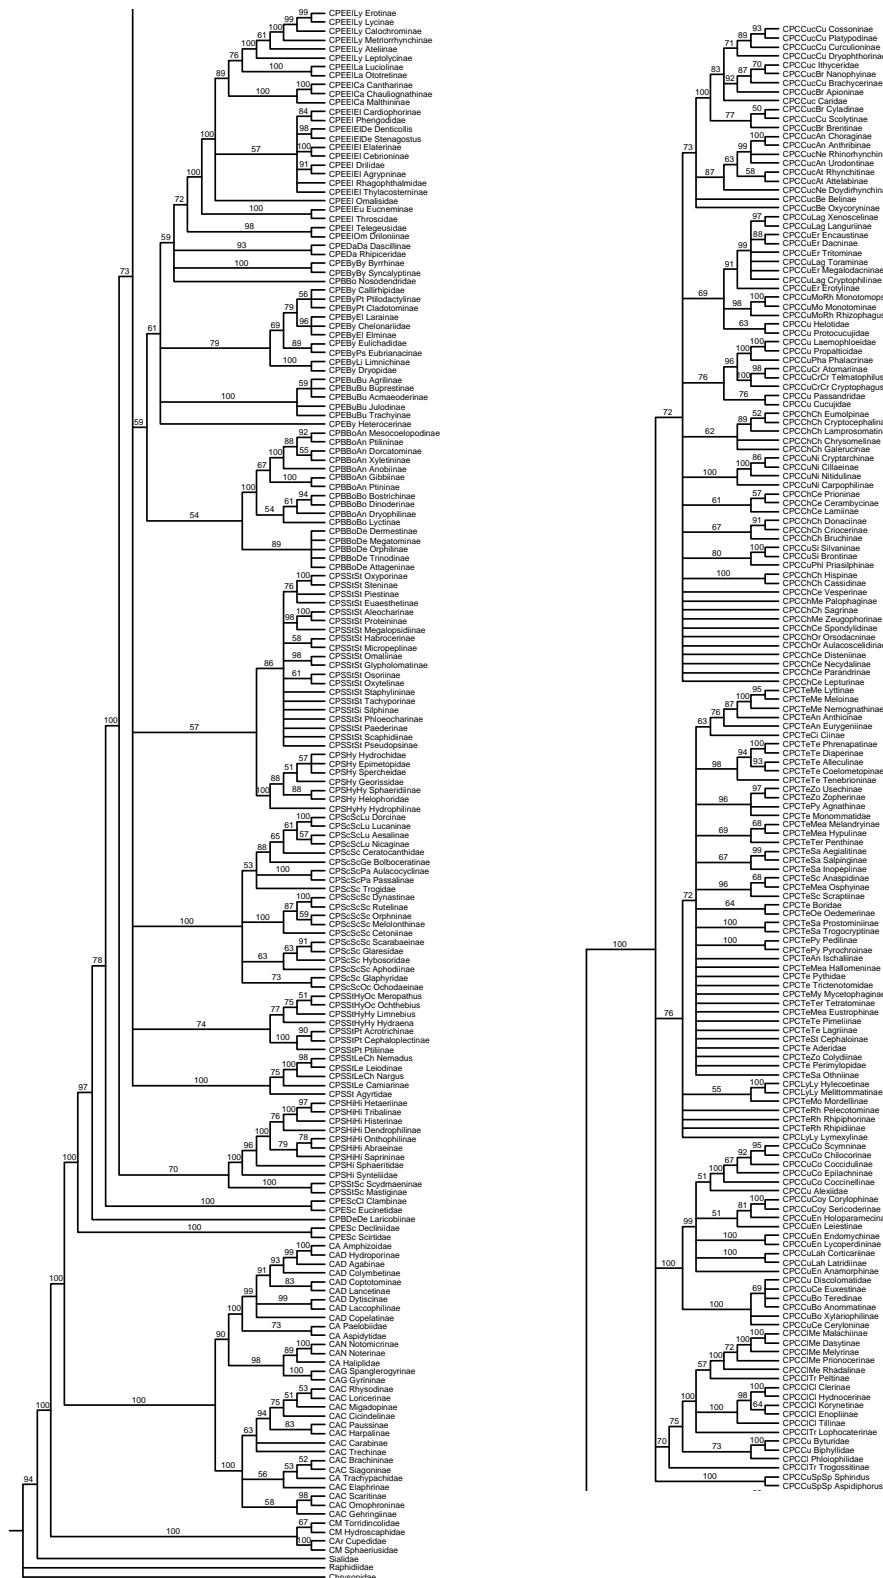

Figure S3. The evolution of feeding strategies in Coleoptera. Feeding types were scored as a uniform state at the level of entire subfamilies, ignoring minority subgroups with different feeding style (see Table S8). Polymorphic scorings are for terminals in which more than one feeding style prevails or the feeding style of the majority of species is uncertain. The moss-feeding Byrrhidae were included in the algivorous group.

Figure S4 (15 pages). The most parsimonious tree from the 1880 taxon matrix of 107238 steps and CI=0.048. The two mitochondrial genes contributed 82234 steps to the combined-analysis tree (RI=0.696 for SSU and RI=0.412 for the mtDNA data sets).

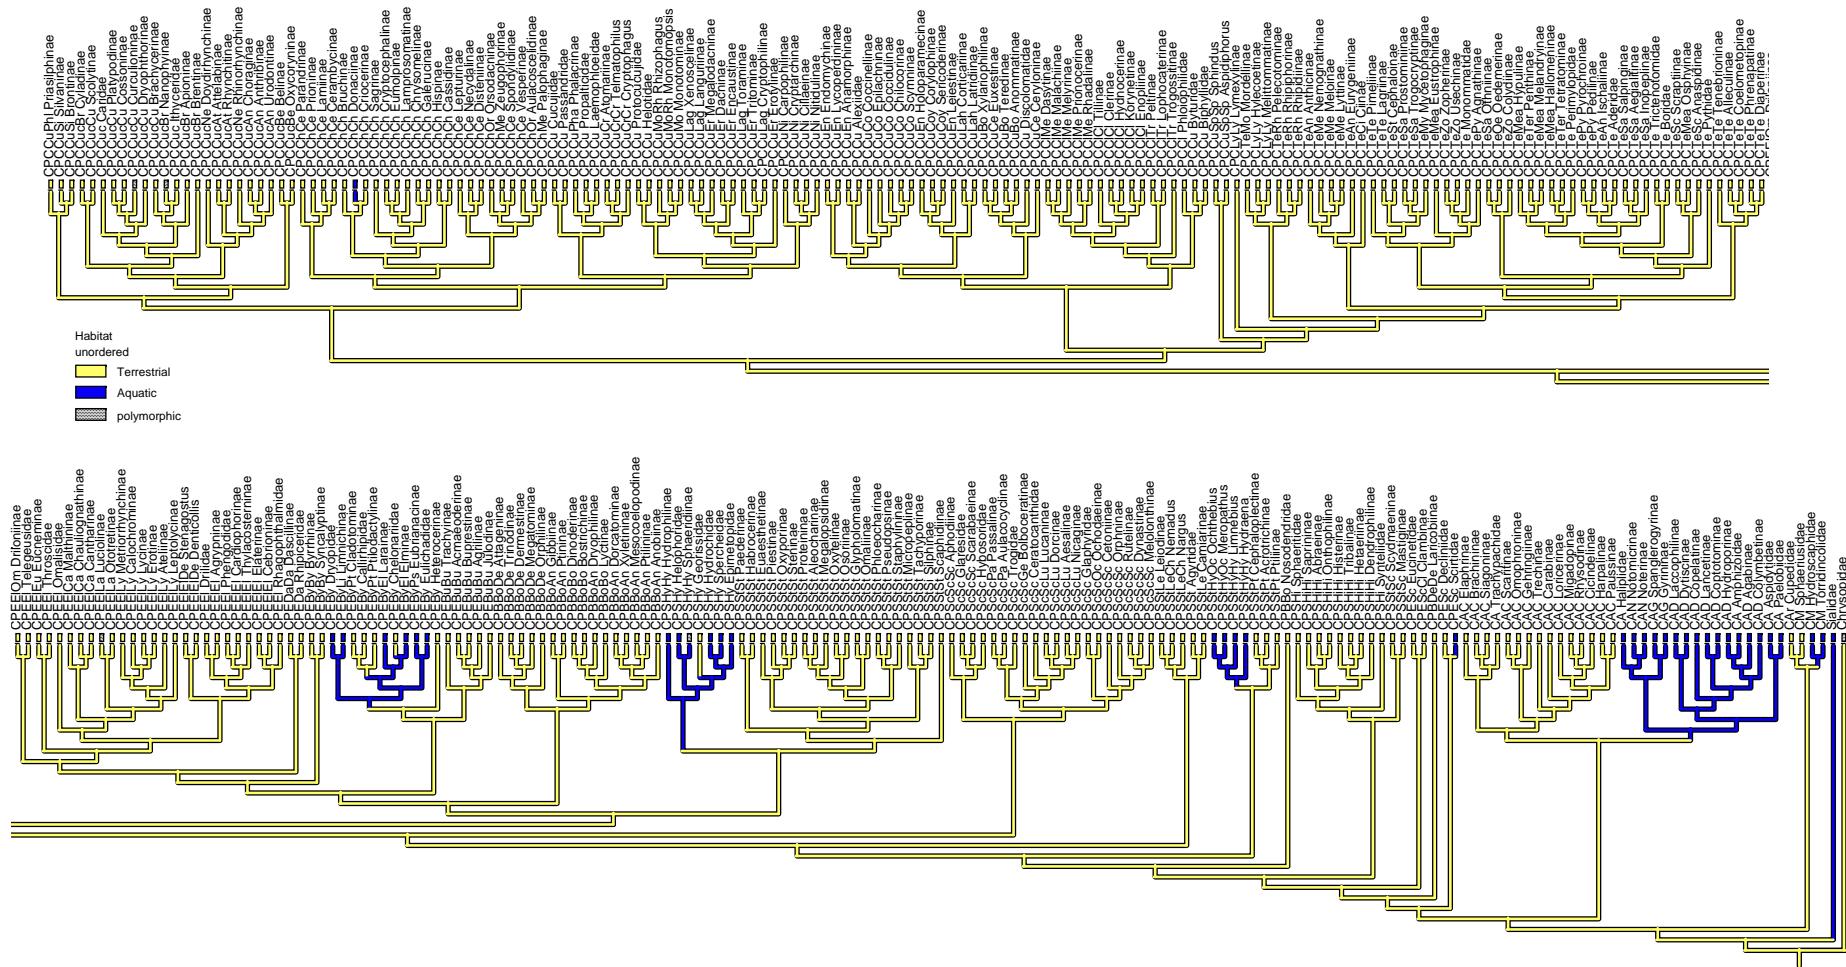

Figure S5. Stationarity of the Bayesian Markov chain Monte Carlo analyses. The log likelihood of each tree is plotted against the number of generations. **A:** Comparison of four chains each using a random topology or a user defined topology as the starting tree for the chains. **B:** Inference chains with user defined starting topology based on traditional classification for families, superfamilies, series and suborders. The likelihood harmonic mean at stationarity was used to evaluate the different runs. Note that even though generation versus likelihood plots suggest apparent stationarity in runs with random starting tree towards the end, they were approximately 500 log likelihood units away from the space sampled by runs 1, 2 and 4 with a user defined starting tree. This shows that for large matrices, 10 million generations is inadequate, and that carefully selected starting trees can substantially reduce the run time (but see contrary findings, S17). Only runs 1, 2 and 4 with a user defined starting tree were used to establish

posterior probabilities in the final trees with the initial 2.5 million generations discarded as burn-in.

Table S2. Taxonomic retention index (RI) for key taxa on various trees. The taxonomic RI is a measure of how traditionally classified groups, when optimized as a single binary character, are consistent with the phylogeny. The tree with 1880 taxa is given in Fig. 1 and S4. Trees with 1691 taxa were obtained after removing all taxa with root-to-tip branches outside of a 95% probability interval for all taxa in the tree (S18). Numbers of taxa were further reduced (1150 taxa) when long branches are identified as any terminal branch or internode beyond the 95% probability interval, followed by removal of all taxa that are terminal to these long branches. The tree with 340 taxa is from the Bayesian analysis (Fig. 2). Note that the removal of long branches resulted only in minor improvements of the consistency of the tree with the classification.

	1880 taxa tree	1691 taxa tree	1150 taxa tree	340 taxa tree

Table S3. Stability of the ‘ancestral five’ under different outgroup sampling. Tests were conducted by selecting a subset of the outgroup taxa to determine if the structure of this part of the tree is stable to taxon choice. Three analyses were conducted either with the representatives of the distant Neuropterida (i.e. the full dataset) or representatives of one of the two suggested closest suborders to Polyphaga, Myxophaga and Adephaga. We then assessed the resulting trees with regard to the position of the ‘ancestral five’ families (Scirtidae, Decliniidae, Derodontidae, Eucinetidae, Clambidae). Key nodes recorded were the monophyly of Polyphaga, the monophyly of Polyphaga excluding the ‘ancestral five’ families and variations of their internal positions. Polyphaga excluding Scirtoidea and Derodontidae was always monophyletic in each of six analyses. The internal relationship of the five families however changed and is an unresolved issue apart from the sistergroup relationships of Scirtidae with Decliniidae and Eucinetidae with Clambidae. Bayesian and parsimony analyses were run as described in Material and Methods for all six datasets except that only two instead of four Bayesian runs were performed for the reduced datasets. M, monophyletic; P, polyphyletic.

Outgroups	Neuropterida	Adephaga	Myxophaga	Neuropterida	Adephaga	Myxophaga
	Bayesian			Parsimony		
No. of taxa in dataset	340	333	305	1880	1867	1640

Table S4. Independent comparisons between clades feeding on living angiosperms and their sister clades with alternative feeding strategies. Below the dashed line, angiosperm feeding clades include some taxa feeding on decaying vegetation (contrast 10), recently dead wood (contrast 11) or fungi (contrast 9) but the majority are herbivores. Wilcoxon test on 11 comparisons; 8 positive, 3 negative, one-tailed P = 0.06. The same but minus last three; 8 comparisons, 5 positive, 3 negative, one-tailed P= 0.27.

	Plant feeding	Diet	No. species	Non-plant feeding	Diet	No. species
1	Byturidae	fruits, flowers	16	Biphyllidae	fungivorous	195
2	Languriidae	stem borers	800	Xenoscelinae	fungivorous, decaying vegetation	100
3	Chrysomeloidea	herbivorous xylophagous	53442	Nitidulidae + Erotylid + Cucujid series	mostly fungivorous	7743
4	Curculionoidea (excl. Belinae+ Oxycoryninae)	herbivorous, xylophagous	59163	Belinae+ Oxycoryninae	gymnosperm feeding	177
5	Zeugophorinae	leaf miners	55	Spondylidinae	gymnosperm feeding	100
6	Epilachninae	herbivorous	1051	Coccidulinae+ Chilocorinae + Scymninae	predacious	3900
7	Dascillinae	roots	80	Rhipiceridae	ectoparasitic on cicadas	57
8	Vesperinae	xylophagous	50	Palophaginae + Auloscelidinae	gymnosperm feeding (and angiosperm)	23
9	Attelabidae + Anthribidae	leaf miners & rollers, seeds, stems, shoots, xylophagous, fungivorous	5132	Doydirhynchinae	gymnosperm feeding	15
10	Melolonthinae+ Orphninae+ Rutelinae+ Dynastinae	herbivorous, saprophagous	16329	Cetoniinae	saprophagous (detritus)	4121
11	Buprestidae	xylophagous, herbivorous, roots, leaf miners	14000	Dryopoidea	saprophagous algivorous	3242

Table S5. Significantly imbalanced sister clades (p<0.01) and information on the clades. To test for the contribution of herbivorous lineages, herbivores (H), herbivores and polymorphic groups that include herbivores (H+HN) and the same but also including xylophagous (H+HN+X) taxa were excluded. The asterisks indicate nodes associated with switches between gymnosperm feeding and angiosperm feeding. Bold: sister comparison 9 retrieved significant imbalance near the base of Polyphaga even when all herbivorous taxa are excluded from the analyses. (This imbalance is picked up by this modified Slowinsky-Guyer test only at slightly higher node levels due to the way the method deals with the ‘trickle-down effect’; see sister comparison 9a and 9b). This finding indicates a highly significant increase in diversification rate in Polyphaga even if all plant-associated species are disregarded. NA=clade not supported in consensus.

	Slowinsky-Guyer Imbalance (p-value)				Sister clades (a vs. b)	Support value	Described number of species	Terrestrial/aquatic	Feeding type

Table S6. Calibration points used for dating the phylogeny of Coleoptera.

	Fossil	Min. age for lineage	Period	Location	Period beginning ¹ ,	Reference
a	Cupedidae	Cupedidae	Triassic, Ladinian	Madygen, Fergana, Kirgisztan	228.0±2.0 my	(S19)
b	Sogdodromeus	Geadephaga	Triassic, Ladinian	Kirgisztan	228.0±2.0 my	(S19)
c	Staphylinidae	Staphylinidae	Triassic, Carnian	Virginia, USA	216.5±2.0 my	(S20)
d	Holcorobeus	Scarabaeoidea	Jurassic, Kimmeridgian	Kazachstan	150.8±4.0 my	(S21)
e	Elaterophanes	Elateridae	Hettangian Jurassic,	Dorset, U.K. Karatau,	196.5±1.0 my	(S22)
f	Praemordella	Mordellidae	Kimmeridgian Jurassic,	Kazachstan	150.8±4.0 my	(S23)
g	Cerambycomima	Chrysomeloidea	Kimmeridgian	Kazachstan	150.8±4.0 my	(S23)

1. Estimated age of period beginnings and errors associated with the dating from Gradstein et al. (24).

Table S7. Average diversification rates of the Coleoptera and number of lineages present at key evolutionary time points. The table presents the net speciation per My across the Coleoptera (Div. Rate) and the number of present-day lineages existing at the Triassic-Jurassic boundary (200 Ma), at the origin of crown group angiosperms (140 Ma) and at the K-T boundary (65 Ma). The ranges for fossil constrained trees were obtained conducting the calculations on the earliest and latest estimate for the dating of geological stage boundaries (Table S6 and ref. S24). Note that at the origin of the angiosperms well over 100 of the modern lineages of beetles were already present. S.P. = Smoothing Parameter. S.E. = Standard error.

S.P.	Div. Rate	S.E.	200 Ma	140 Ma	65 Ma
Fixed root					
1	0.054	0.002	42	162	310
10	0.048	0.0017	68	205	316
100	0.059	0.0023	36	145	301
1000	0.068	0.0029	28	118	290
Fossil constrained					
1	0.051-0.052	0.0019	52	178-180	313
10	0.049-0.050	0.0018	52-56	189-193	313-314
100	0.046	0.0017	76	210-211	316
1000	0.056	0.0022	44-46	158-161	305-306

Table S8. Number of described species, generalized feeding habits and terrestrial or aquatic habitat for terminal taxa. Data were compiled from various literature sources and direct counts from recent catalogs. Where modern revisions were not available, numbers were estimated based on our knowledge of the groups. An asterisk indicates where species counts available at the family level were split equally between subfamilies used as terminals in the tree. Numbers of described species underestimate the actual species counts to various degrees because the intensity of taxonomic work has differed across groups. Habitat: 0=terrestrial, 1=aquatic. Feeding habit (based on the main feeding stage, normally the larval stage): 1=fungivorous, 2=herbivorous, 3=saprophagous, 4=predacious, 5=xylophagous, 6=parasitoid, 7=algivorous and bryophagous (Byrrhidae).

D) Alignment Files

Alignment S1 (separate text file). 1880 taxon three gene alignment matrix. The blast-based alignment of SSU and the ClustalX alignments of *rrnL* and *cox1* concatenated together to form the three gene matrix used in the parsimony analysis presented in Fig. 1. Alignment provided in NEXUS format.

Alignment S2 (separate text file). 340 taxon three gene alignment matrix. The three gene alignment matrix used in the Bayesian analysis to generate the tree in Fig. 2. SSU and *rrnL* were aligned guided by secondary structure with unalignable sites excluded, whilst *cox1* was length invariable for the selected taxa.
